# C - Variable Arguments

Sometime you may come across a situation when you want to have a function which can take variable number of arguments i.e. parameters, instead of predefined number of parameters. The C programming language provides a solution for this situation and you are allowed to define a function which can accept variable number of parameters based on your requirement. The following example shows the definition of such a function.

```
int func(int, ... )
{
    .
    .
    .
}

int main()
{
    func(1, 2, 3);
    func(1, 2, 3, 4);
}
```

It should be noted that function **func()** has last argument as ellipses i.e. three dots (...) and the one just before the ellipses is always an **int** which will represent total number variable arguments passed. To use such functionality you need to make use of **stdarg.h** header file which provides functions and macros to implement the functionality of variable arguments and follow the following steps:

Define a function with last parameter as ellipses and the one just before the ellipses is always an **int** which will represent number of arguments.

Create a **va\_list** type variable in the function definition. This type is defined in stdarg.h header file.

Use **int** parameter and **va\_start** macro to initialize the **va\_list** variable to an argument list. The

macro **va\_start** is defined in **stdarg.h** header file.

Use **va\_arg** macro and **va\_list** variable to access each item in argument list.

Use a macro **va\_end** to clean up the memory assigned to **va\_list** variable.

Now let us follow the above steps and write down a simple function which can take variable number of parameters and returns their average:

```
#include <stdio.h>
#include <stdarg.h>

double average(int num,...)
{
    va_list valist;
    double sum = 0.0;
    int i;

    /* initialize valist for num number of arguments */
    va_start(valist, num);

    /* access all the arguments assigned to valist */
    for (i = 0; i < num; i++)
    {
        sum += va_arg(valist, int);
    }

    /* clean memory reserved for valist */
    va_end(valist);

    return sum/num;
}

int main()
{
    printf("Average of 2, 3, 4, 5 = %f\n", average(4, 2,3,4,5));
    printf("Average of 5, 10, 15 = %f\n", average(3, 5,10,15));
}
```

When the above code is compiled and executed, it produces the following result. It should be noted that the function **average()** has been called twice and each time first argument represents the total number of variable arguments being passed. Only ellipses will be used to pass variable number of arguments.

```
Average of 2, 3, 4, 5 = 3.500000
Average of 5, 10, 15 = 10.000000
```
